

# Quantification

---

RNA-seq data analysis

Johan Reimegård | 15-November-2021

# Count the reads

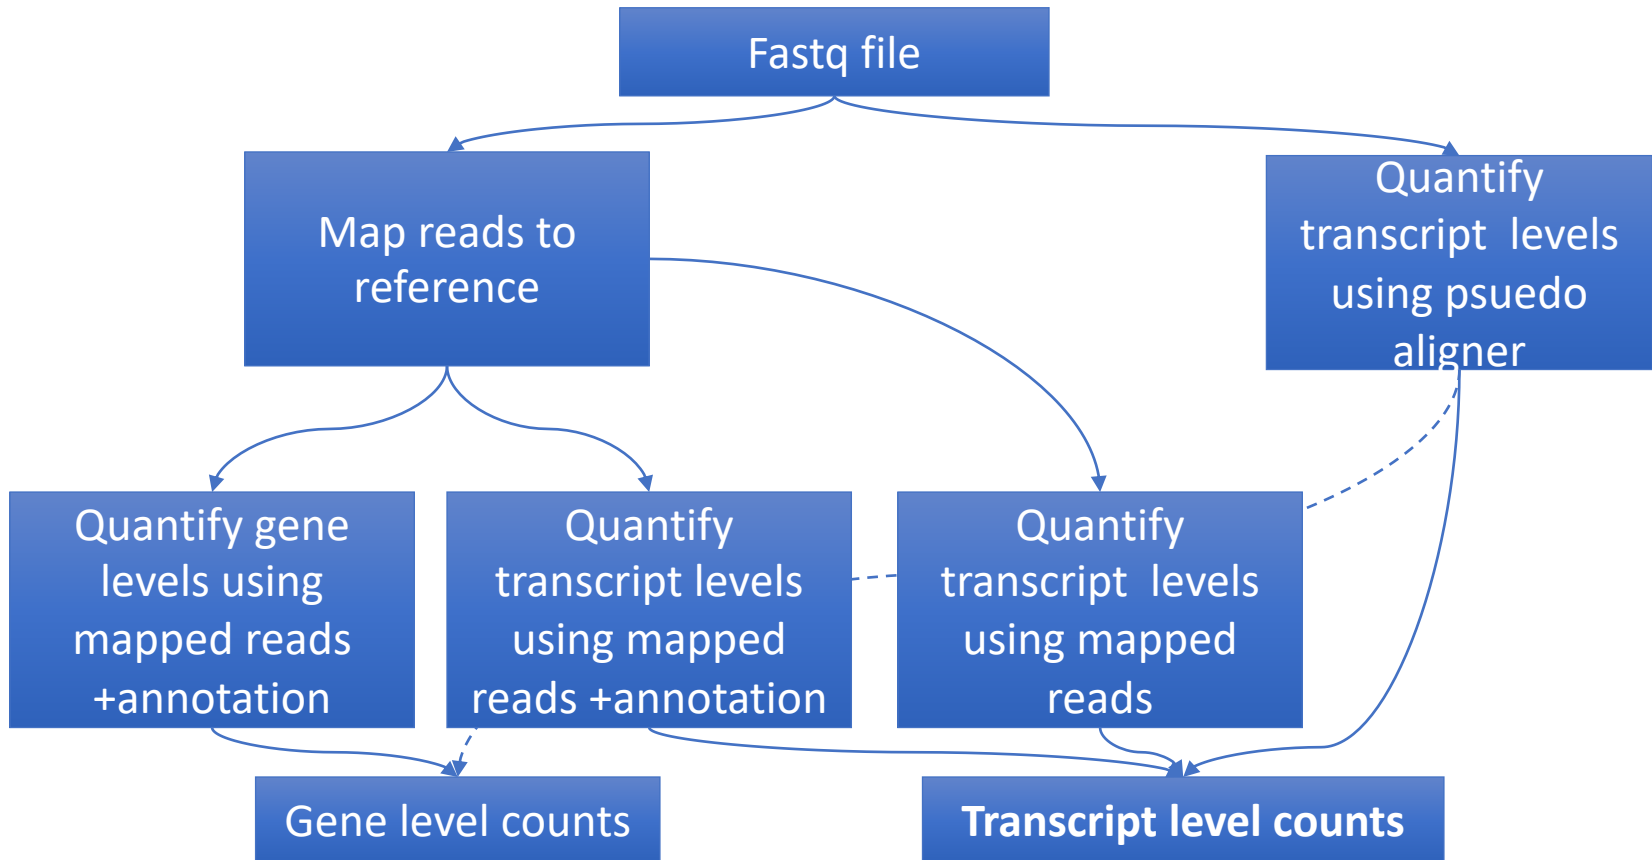

- Read counts = gene expression
- Reads can be quantified on any feature (gene, transcript, exon etc)
- Intersection on gene models
- Gene/Transcript level

 [featureCounts](#), [HTSeq](#)

# Different paths to get a count table

Good news is that they are all working very well!!

# Gene expression estimates

- Expression estimates on gene level
- Expression estimates on transcript level

# Gene level analysis

# Expression levels are similar between RT-qPCR and RNA-seq data

**Figure 1.** Gene expression correlation between RT-qPCR and RNA-seq data. The Pearson correlation coefficients and linear regression line are indicated. Results are based on RNA-seq data from dataset 1.

# Lowly expressed genes are more problematic to identify using RNA seq

Most problems are consistent so they disappear when you do diff-exp analysis

# Transcript level analysis

# Transcript level analysis

# Methods used in paper

**Table 1** Run time metrics of each method on 50 million paired-end reads of length 76 bp in an high performance computing cluster

	Memory (Gb)	Run time (min)	Algorithm	Multi-thread
Cufflinks	3.5	117	ML	Yes
RSEM	5.6	154	ML	Yes
eXpress	<u>0.55</u>	30	ML	No
TIGAR2	<b>28.3</b>	<b>1045</b>	VB	Yes
kallisto	3.8	7	ML	Yes
Salmon	6.6	6	VB/ML	Yes
Salmon_aln	3	7	VB/ML	Yes
Sailfish	6.3	<u>5</u>	VB/ML	Yes

For methods that support multi-threading, eight threads were used. For alignment-free methods (Kallisto, Salmon and Sailfish), a mapping step was included. The best performer in each category is underlined and the worst performer is in bold *ML* Maximum Likelihood, *VB* Variational Bayes

# Isoform quantification problematic for genes with many isoforms

**Fig. 2** Comparisons of the overall performance among different methods and the impact of the number of transcripts on the accuracy of isoform quantification. **a** Pearson correlation coefficient. **b** mean absolute relative differences and **c-d**) The above metrics were broken into separate groups according to the number of annotated transcript isoforms for each gene. The number of transcripts in each group is shown in figure legends. The accuracy metrics were calculated by comparing the estimated counts with the “ground truths” in simulated dataset

# Results are very similar between methods

**Fig. 5** Pairwise correlation of estimated TPM values for all transcripts between methods for the HBRR-C4 sample. The distribution of transcripts' TPMs from each method was plotted on the diagonal panels. Pairwise density plots and  $R^2$  values are shown in the lower and upper triangular panels, respectively.  $R^2$  values over 0.9 are in *bold*. Methods are grouped using hierarchical clustering

**Thank you. Questions?**
