

Sequentially Markovian Coalescence

André E. R. Soares

The idea

To reconstruct the demographic history of a species from genome sequences.

The most common methods to do so

PSMC

The most common methods to do so

PSMC

Unphased genome
One diploid individual

MSMC

Phased genomes
Many individuals

Coalescence methods

So it has some **

Some assumptions and particularities:

- Neutral evolution
- Panmitic population: equal coalescence probabilities for all pairs of lineages
- **Coalescence rate is related to population size.** (as seen earlier)

If we have a genealogy that shows when the coalescent events happened, we then can infer the population size of a population.

Sequentially Markovian Coalescent

Think different

Traditional coalescence methods

- They work backwards
- They build full genealogies from modern/extant samples.

Sequentially Markovian Coalescence

- They go along the genome
- It builds a "local" genealogy for each locus on the genome.

How does it work?

PSMC uses a HMM

HMM = Hidden Markov Model

How does it work?

Some SMC methods will use a HMM

Some states that change with time

How does it work?

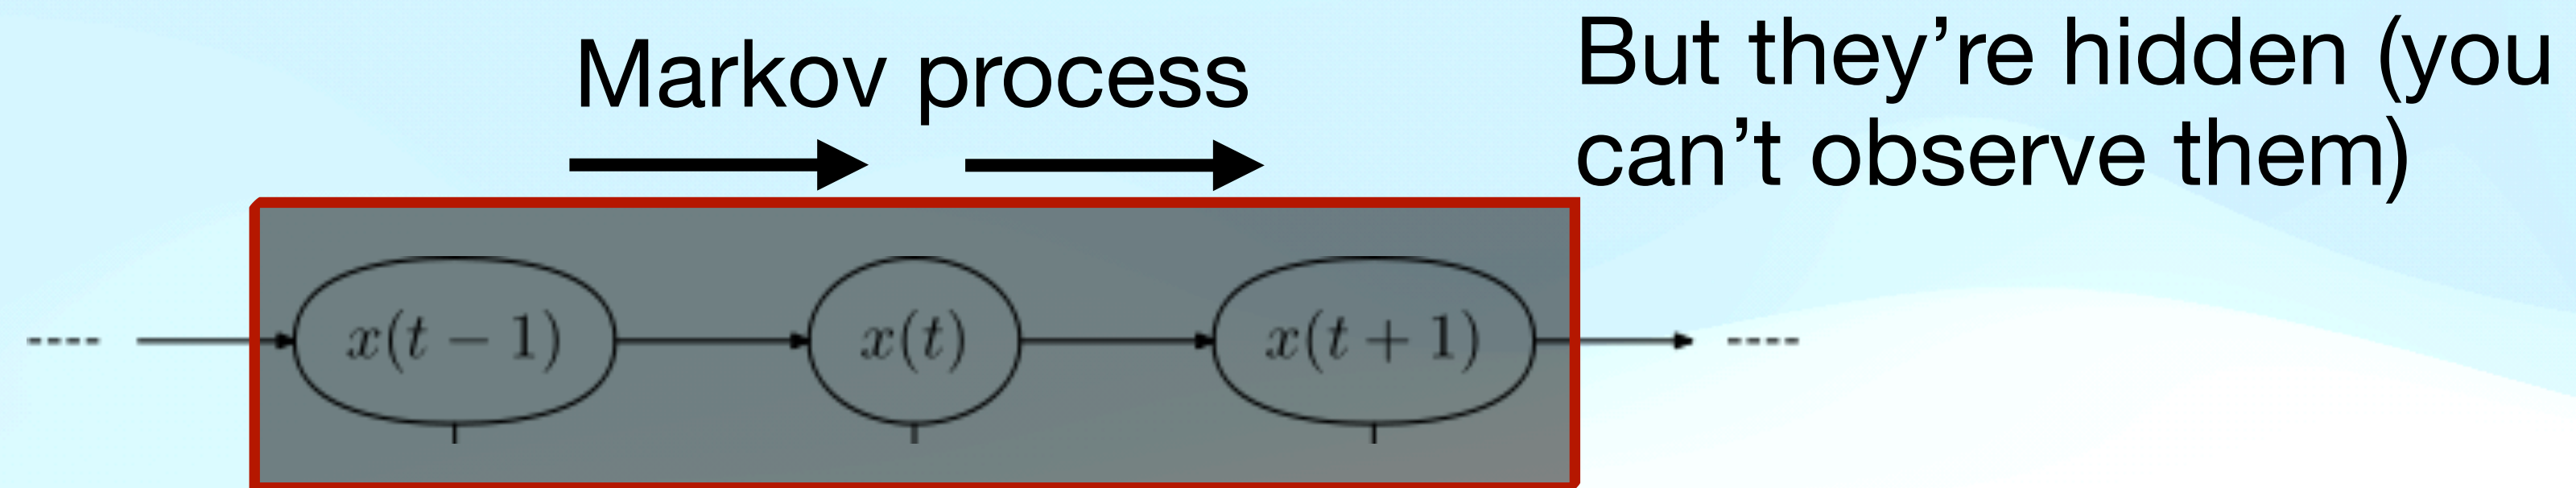

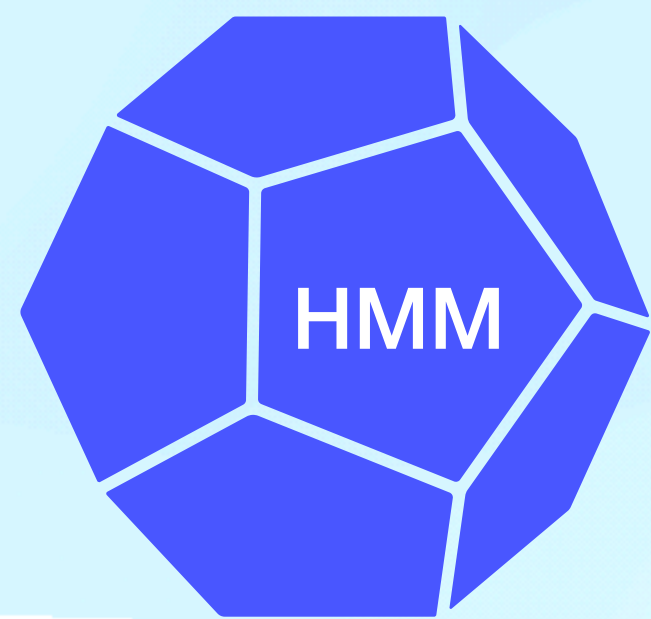

Some SMC methods will use a HMM

But they're hidden (you can't observe them)

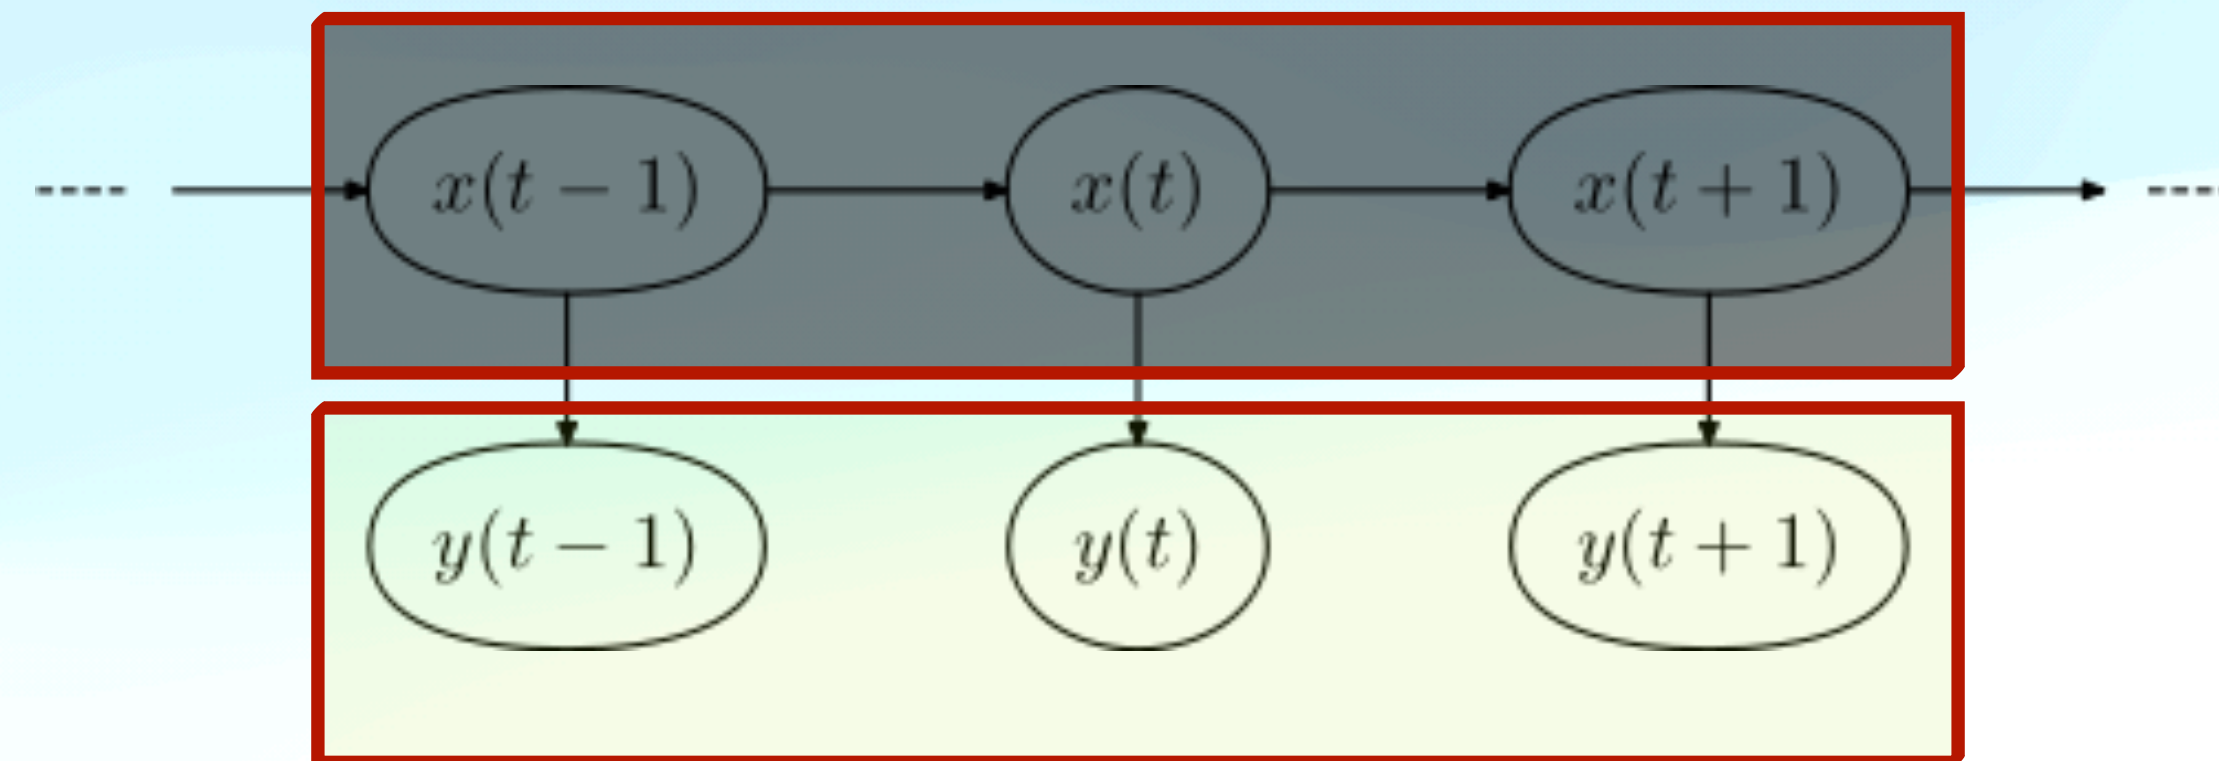

How does it work?

Some SMC methods will use a HMM

How does it work?

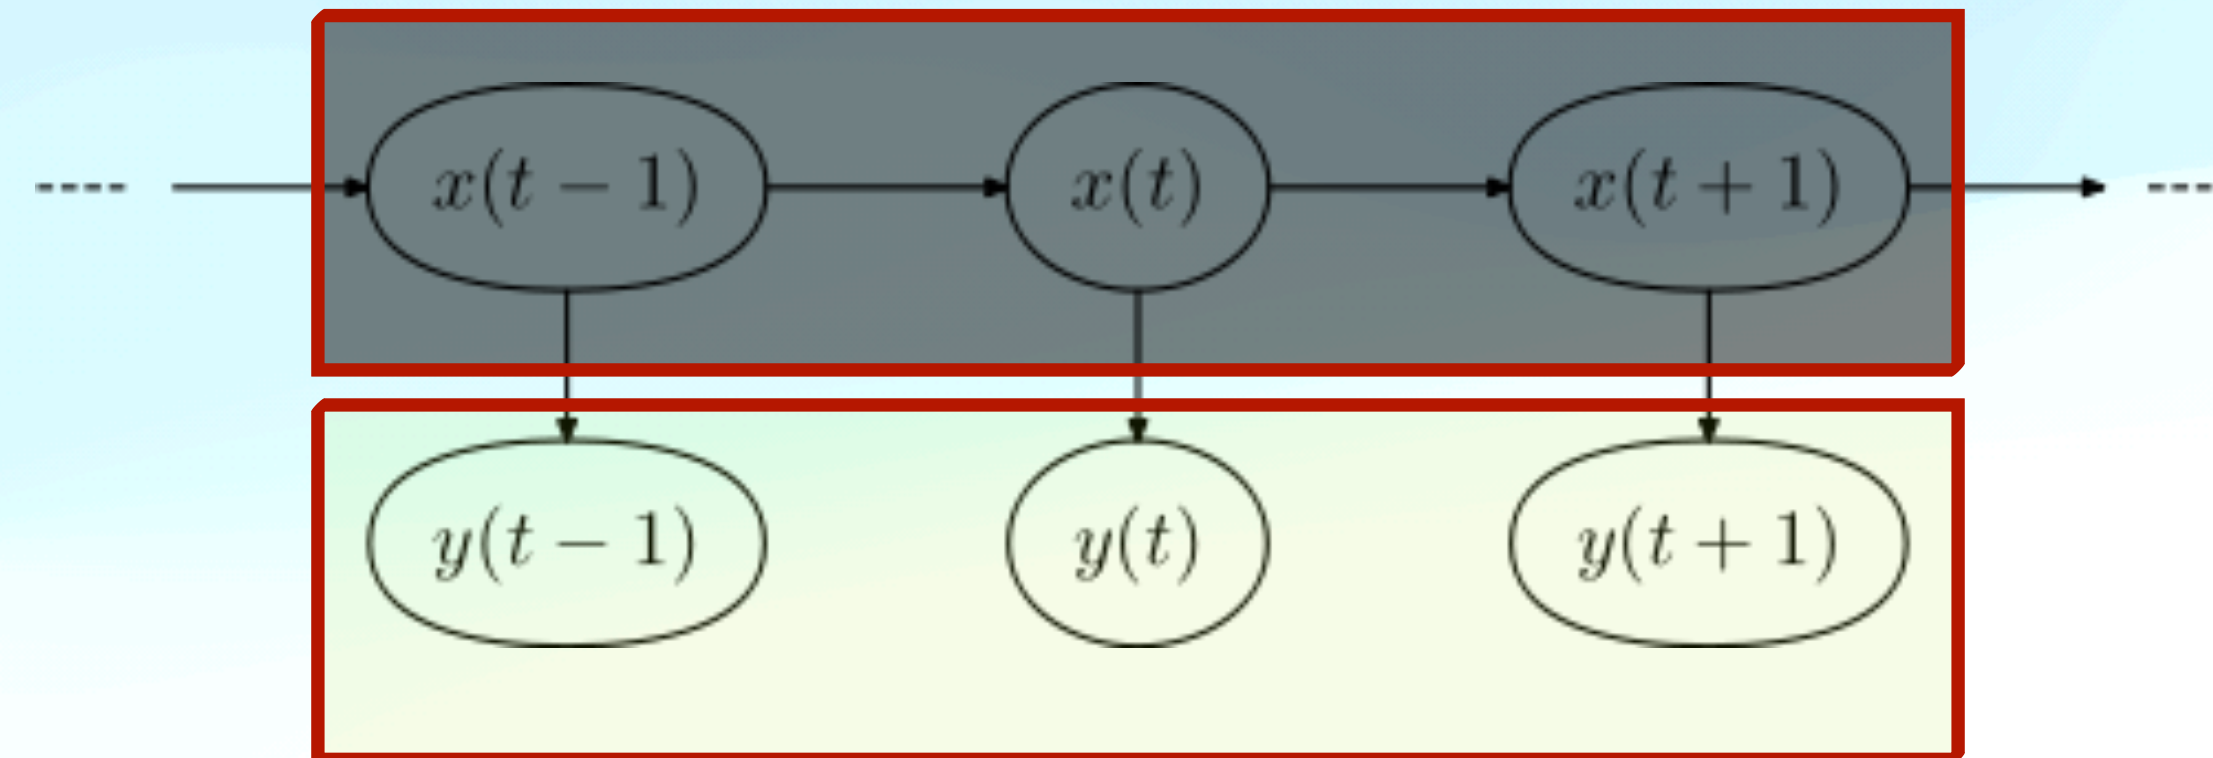

Some SMC methods will use a HMM

But you can observe
something connected to them

How does it work?

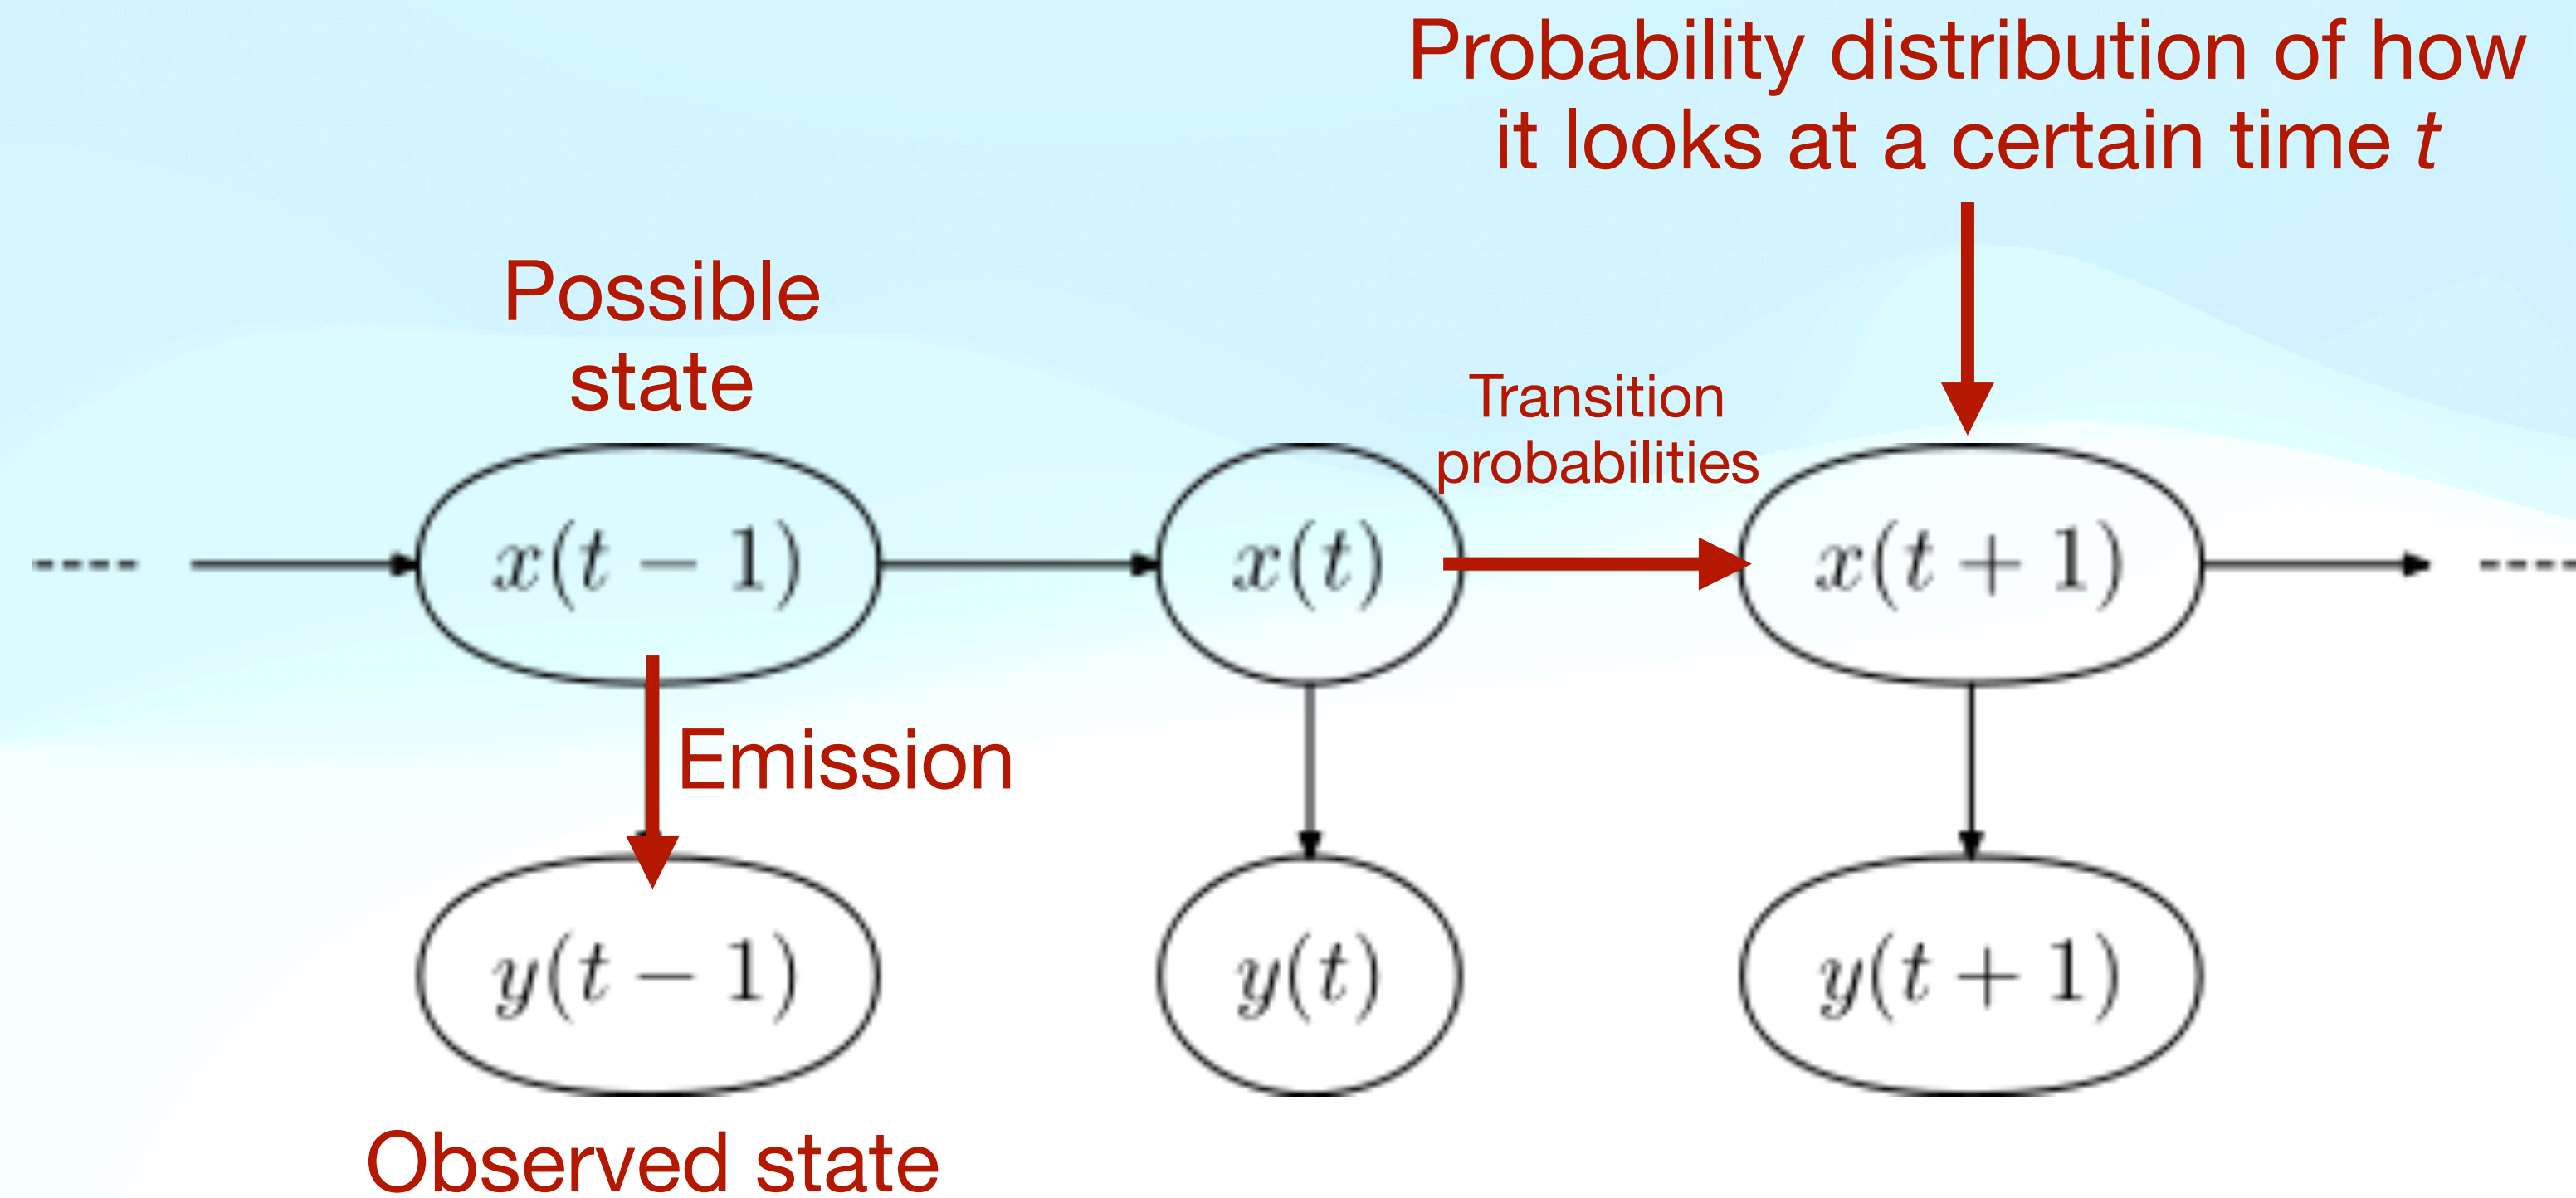

Some SMC methods will use a HMM

It's really powerful for dynamic systems and is used a lot in computational biology (annotation, etc)

How does it work?

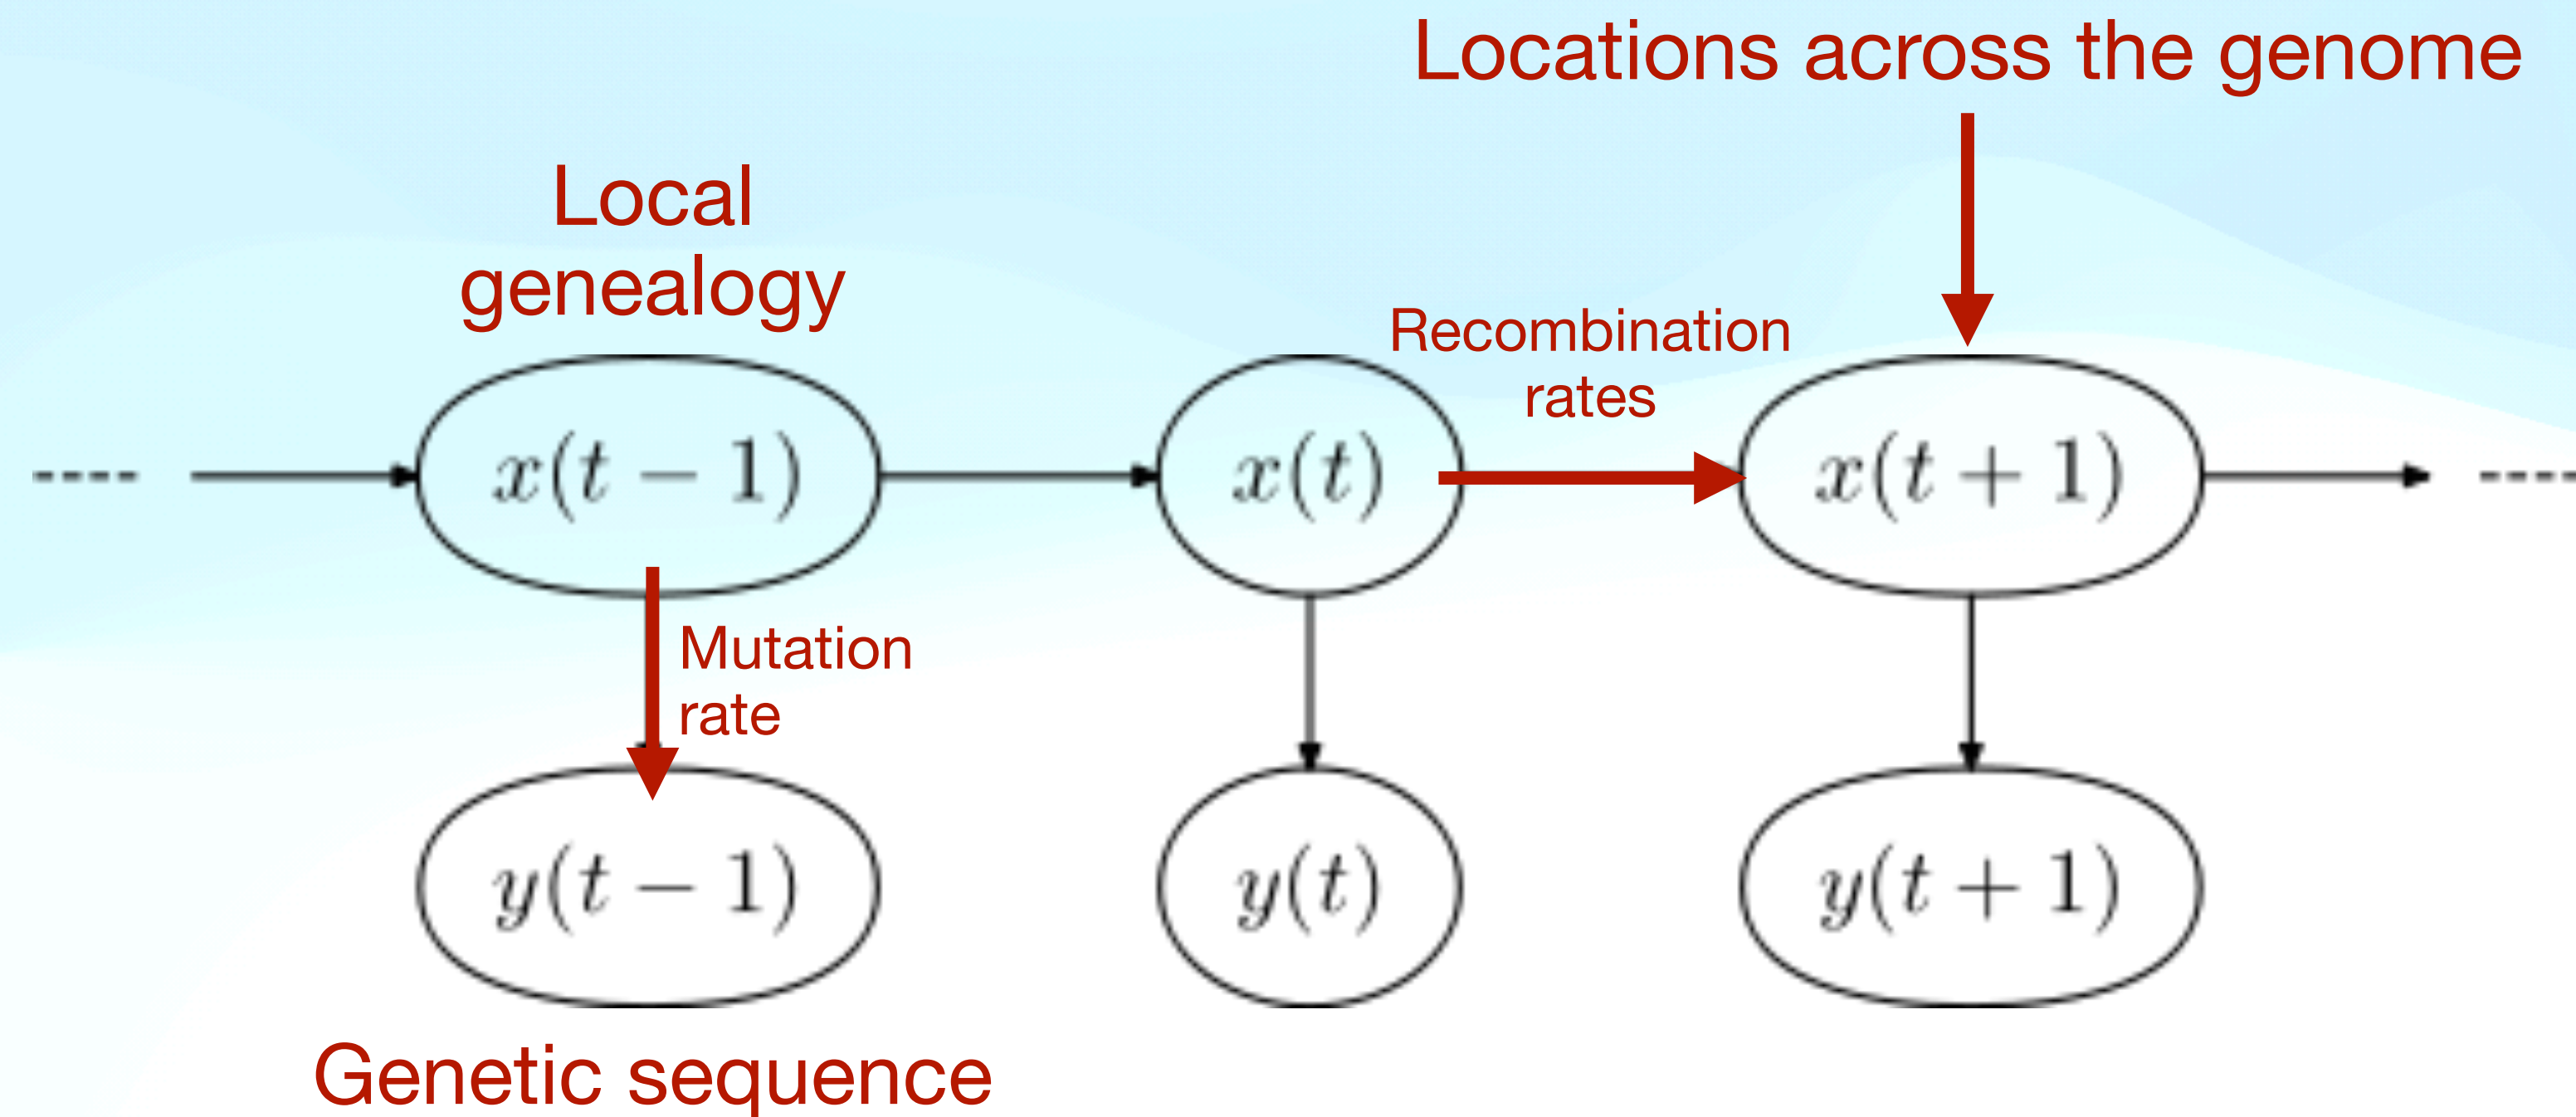

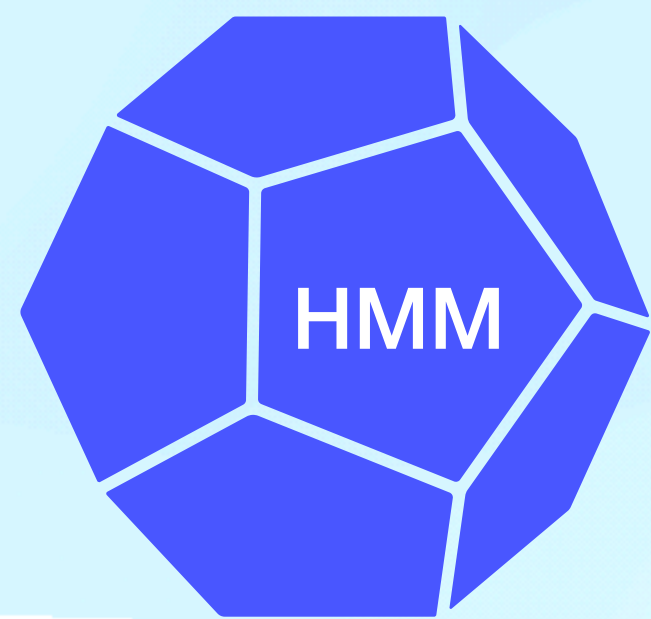

Some SMC methods will use a HMM

Naming each part of it...

How does it work?

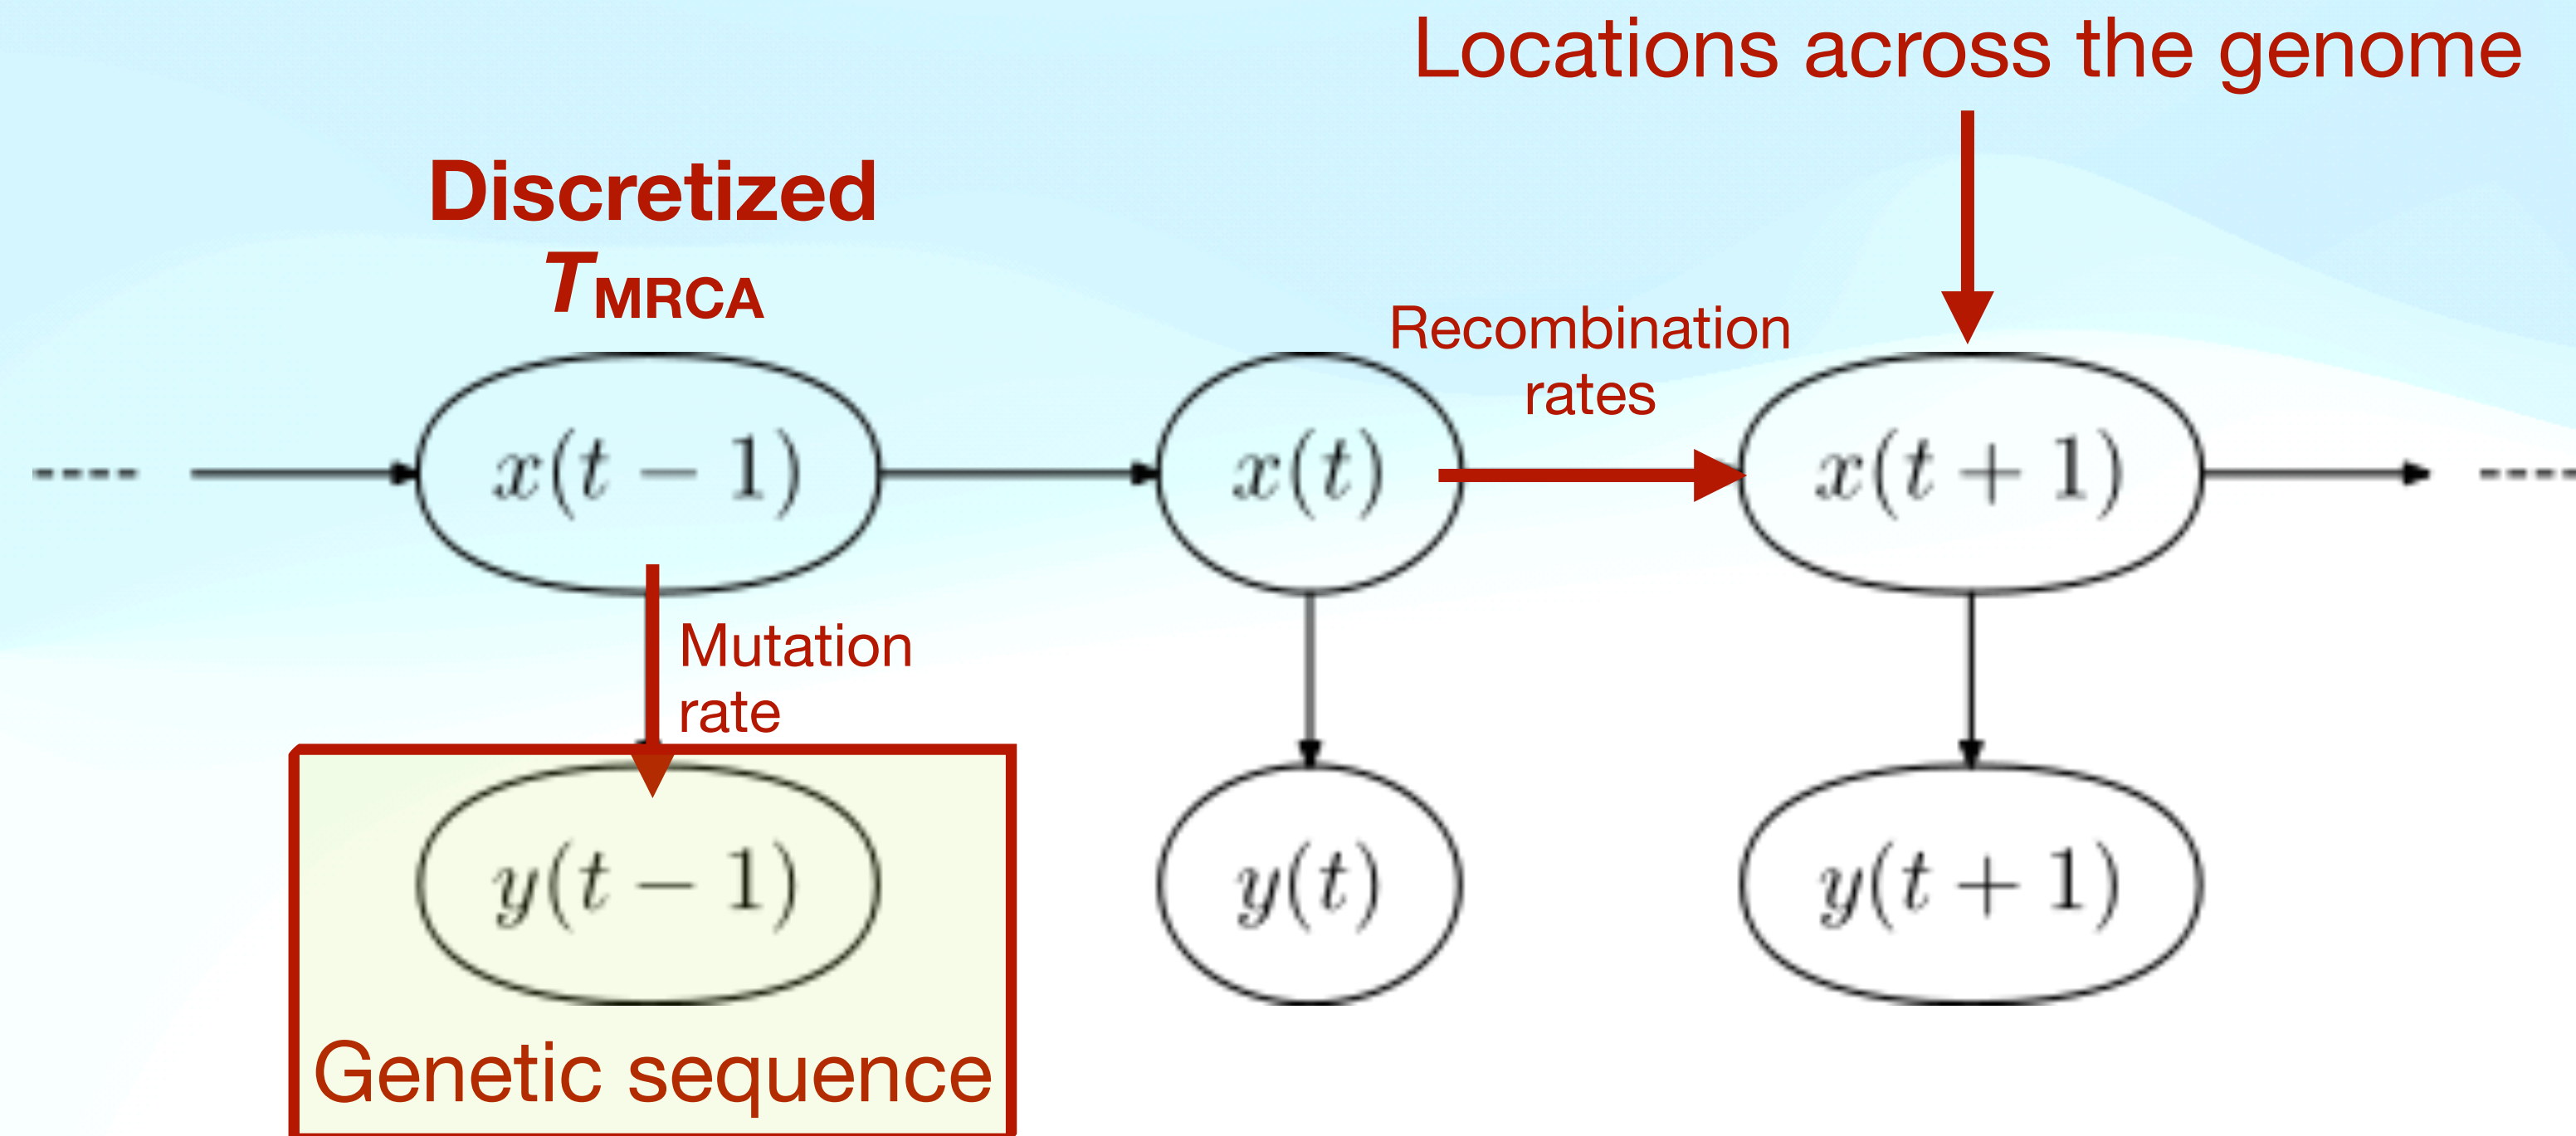

Some SMC methods will use a HMM

How SMC methods work

How does PSMC work?

Some SMC methods will use a HMM

- It creates 100 bp windows
- 1 for hets, 0 for homs

How does SMC work?

In a whole genome we have...

The SMC is capable of calculating the probability of recombination breakpoints.

 Nucleotides states

Recombination breakpoints

Since a "tree" between two sequences is known,
the only variable that change is T_{MRCA} .

 Nucleotides states

Recombination breakpoints

So when PSMC runs...

It writes down the likelihood of getting the **genomic data**, the **recombination break points**, and the T_{MRCA} along the sequence, per window (default is 100 bp).

You can count how many events happened at a certain time period

PSMC and MSMC use this information to reconstruct the effective population size through time

You can count how many events happened at a certain time period

PSMC and MSMC use this information to reconstruct the effective population size through time

PSMC and MSMC use this information to reconstruct the effective population size through time

You can count how many events happened at a certain time period

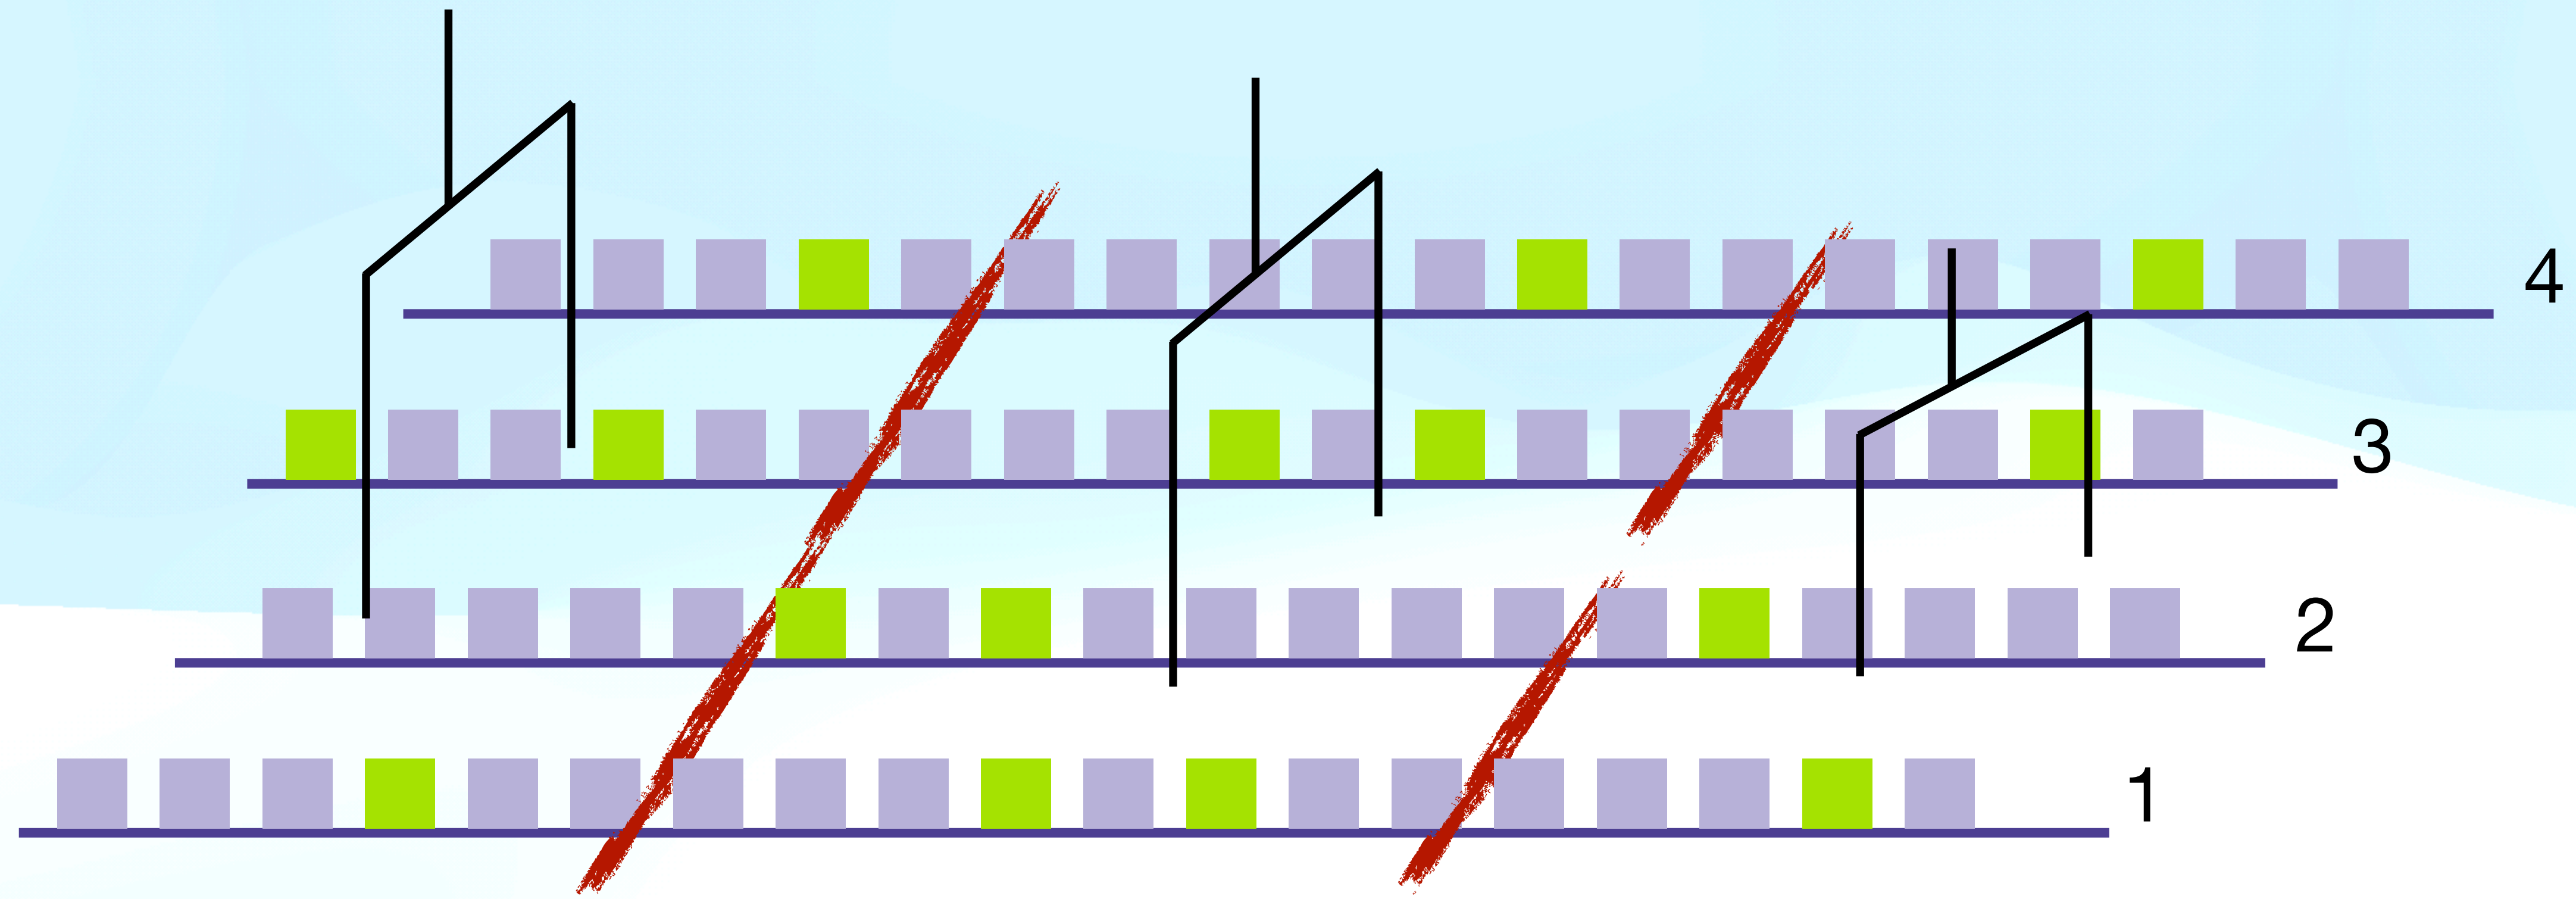

PSMC and MSMC use this information to reconstruct the effective population size through time

What about MSMC?

PSMC: Local genealogy is the time to the T_{MRCA} , because only one tree

MSMC: Uses only some of the local trees, the ones that describe the T_{MRCA} of two alleles at a locus

What does it look like?

* You need to know the **generation time** and **mutation rate** to scale the graph.

PSMC plot

PSMC plot

PSMC plot - example 01

What do you see?

PSMC: the weak points

- It's really dependable on proper generation times and mutation rates;
- Sudden drops in population will show as a steady decline over time instead of a sudden bottleneck;
- Population structure will strongly affect the results (as it affects coalescence times);
- Not great with zoo animals;
- Doesn't have a framework for testing hypotheses, must use bootstrap replicates instead.

PSMC: the weak points

Factors that affect the coalescent rates will affect the PSMC too, like natural selection and nonrandom mating.

PSMC vs MSMC

- It tends to out-perform PSMC even in single genomes;
- Multiple individuals help increase the chance for alleles with coalescence events in the recent past;
- Deep coalescences are relatively rare in all cases.

PSMC and beyond

MSMC2: Expands on MSMC, that's limited to eight samples in most cases.

SMC++ (Terhorst et al. 2017): higher accuracy

ASMC (Palamara et al. 2018): 2-3x faster

XSMC (Ki & Terhorst, 2020)

Gamma-SMC (Schweiger & Durbin, published in Advance August 10, 2023): Up to 20x faster, can detect loci under positive selection.
